

Problem Description:

You are tasked to build a machine learning model that predicts a student's exam score based on their study habits and academic performance indicators. Using a dataset containing student records, implement a **Multiple Linear Regression model** using Python.

The dataset file is named:

student_linear_regression_dataset_1000.csv

It contains the following columns:

- Hours_Studied – number of hours the student studied
- Attendance_Percent – percentage of class attendance
- Assignments_Completed – number of completed assignments
- Exam_Score – final exam score (target variable)

Required Tasks:

1. Load the dataset using **pandas**.
2. Select the input features:
 - Hours_Studied
 - Attendance_Percent
 - Assignments_Completed
3. Assign the target variable:
 - Exam_Score
4. Split the dataset into training and testing sets using an **80/20 split** with random_state=42.
5. Train a **Linear Regression model** using the training data.
6. Evaluate the model using the test data.
7. Display the following outputs:
 - Model intercept
 - Model coefficients
 - R² score of the model

Expected Output (Format Example):

Intercept: 12.45

Coefficients: [3.21, 0.85, 2.67]

R² Score: 0.89

Constraints:

- You must use scikit-learn library.
- Do not modify the dataset structure.
- Ensure reproducibility using random_state=42.

Bonus Challenge (Optional):

Extend the program to allow user input so that the model can predict an exam score based on:

- Hours studied
- Attendance percentage
- Assignments completed
